

Real single neurons at the transient↔sustained extremes

GLM TF kernel = each cell's deconvolved response to a unit change in temporal frequency. TOP: SUSTAINED (stays elevated ~0.4–0.7 s) BOTTOM: TRANSIENT (a brief blip)
 Shaded band = 95% CI (trial bootstrap, 200×). Grey = the same cell's model-free FAST–SLOW pulse contrast + its 95% CI (background-cancelled): it tracks the kernel's shape but is far noisier — model-free corroboration, and why the deconvolving GLM is the better estimator.

SUSTAINED fwhm=0.404s
